Chapter 1

Executive Summary

Key takeaway: This report records a bounded system-review/documentation run after a large local refactor. The run fixed the live drift found in review, documented intentional draft deletion, preserved formal evidence, and verified that project literature and repository state describe the same agentic development trail.

The trigger was a local-vs-remote review of a broad AgenticSystem refactor. The review found that the main architecture direction was correct: internal agent rules, state, tools, tests, and report sources now live under `agents/`; public runtime and downloadable artifacts live under `site/`; root is limited to platform and crawler entrypoints.

The review also found three small but real live inconsistencies and one evidence decision that needed explicit documentation:

1. `agents/rules/core/ci-rules.md` still described old docs-lint and Lychee config paths.
2. `site/content/projects.json` still named `public-status.json`, although the generated public status file is now `site/data/status.json`.
3. `agents/reports/tex/Makefile` still pointed humans to the old `content/reports/tex/root`.
4. Discarded social/profile draft bodies were intentionally not restored; they are candidate outputs, not durable evidence or future steering rules.
5. Browser validation exposed a direct clean-route render defect, which was fixed with root-absolute shell assets and pathname-aware pushState routing.

This report exists because the project claim is stronger than "a pretty prompt." Agentic-CareerBoost is meant to be a repository-backed record of agentic development: rules, failures, corrections, evidence, validation, and public artifacts must line up.

Chapter 2

Authority Boundary

Key takeaway: Reports and state are evidence. They explain what happened. They do not override current user scope or stable rules.

The reconciliation uses the existing authority model:

Table 2.1: Authority and evidence surfaces after reconciliation.

Surface	Meaning
agents/rules/**	Authoritative behavior layer: core truth, workflows, roles, and templates.
agents/state/**	Evidence and status layer: logs, research, summaries, current state, and human queues.
agents/reports/tex/**	Formal source documents for human-facing proof artifacts.
site/files/reports/**	Published PDFs intended to remain visible in the repository and public site.
agents/work/social/**	Working social material; future drafts may live here, but discarded old draft bodies do not steer future copy.

The key correction is not deletion for its own sake. It is category discipline. Historical logs, summaries, research, and LaTeX reports are retained as proof. Old discarded profile and social drafts are not retained as reusable context because they can poison future copy and were never approved publication facts.

Chapter 3

Evidence Classification

Key takeaway: The refactor is safe only if the repository can explain what was kept, what moved, what was discarded, and why.

Table 3.1: Deletion and migration classification.

Category	Examples	Decision
Preserved evidence	Sprint logs, research, summaries, closure notes, formal report sources	Kept under <code>agents/state/**</code> or <code>agents/reports/tex/**</code> ; non-authoritative but inspectable.
Migrated public artifacts	Report PDFs, CV PDF, reusable public images	Moved to <code>site/files/**</code> or <code>site/assets/**</code> so public runtime owns public files.
Discarded candidate outputs	Old profile consistency drafts, LinkedIn reactivation drafts, branding/social draft bodies	Intentionally deleted; they were candidate copy, not approved evidence or future instruction.
Removed duplicates and generated mirrors	Manual public status mirrors, duplicate public asset paths, old root work areas	Removed or replaced by generated <code>site/data/status.json</code> and canonical path references.
Archived origin/audit material	Bootstrap origin files and prior audit reports	Retained under archive paths as historical evidence, not current operating rules.

The discarded drafts remain recoverable from Git history if a human deliberately asks for archaeology, but they are not live material. That is the intended behavior.

Chapter 4

Failure Ledger

Key takeaway: The project record is more credible when it keeps the failures that forced the correction.

Table 4.1: Failures and friction recorded by this reconciliation.

Event	What happened	Resolution
Large refactor risk	The working tree removed or moved more than two hundred tracked paths, so hidden evidence loss was plausible.	Review mapped deleted paths to new successors and classified intentional losses.
CI rule drift	Rule docs still mentioned old Markdown/Lychee config shape.	Updated CI rules to match <code>required-ci</code> , <code>advisory docs-lint</code> , and <code>.github/lychee.toml</code> .
Public copy drift	Project page copy still said <code>public-status.json</code> .	Updated copy to <code>status.json</code> and added regression coverage.
Report-root drift	Makefile comment still referenced <code>content/reports/tex/</code> .	Updated comment to <code>agents/reports/tex/</code> and added regression coverage.
Clean-route runtime drift	Direct loads of clean routes such as <code>/projects/agentive-career-boost</code> did not render the intended route during browser validation.	Root shell assets now use <code>root-absolute /site/...</code> URLs, and the router reads <code>location.pathname</code> plus <code>pushState</code> navigation.
Sandbox friction	Read-only inspection commands hit sandbox failures; elevated read-only commands and an absolute Git path were required.	Recorded as tooling friction, not project failure.
Git PATH friction	Escalated PowerShell did not have <code>git</code> on PATH.	Used <code>C:/Program Files/Git/cmd/git.exe</code> for read-only Git inspection.
LaTeX toolchain variance	Local <code>latexmk</code> was unavailable during validation.	Local build script fell back to three-pass <code>pdflatex</code> ; CI still uses the configured LaTeX action.

Chapter 5

Validation Ledger

Key takeaway: The reconciliation closes only if source, public copy, tests, links, site validation, and formal PDFs agree.

The closure validation for this run is:

Table 5.1: Validation commands and status.

Command or check	Status	Evidence meaning
<code>python agents/tools/export_status.py</code>	PASS	Regenerates <code>site/data/status.json</code> from state evidence.
<code>python agents/tools/validate_static.py</code>	PASS	Confirms root entrypoints, runtime files, routes, and public file refs resolve.
<code>bash agents/tools/validate_links.sh</code>	PASS	Confirms live internal Mark-down references resolve.
<code>python -m pytest agents/tests -q</code>	PASS	Confirms structural and regression guard tests pass.
<code>./build-local.ps1 -Target all</code>	PASS	Confirms every report/CV source compiles locally; <code>pdflatex</code> fallback used when <code>latexmk</code> is unavailable.
Browser/public sanity check	PASS	Confirms key routes load without console errors or broken images after report links and content changes.

The pass status is intentionally tied to concrete commands, not confidence. If a future run changes a public route, report source, or state exporter, the same surface-specific validation must be repeated.

Chapter 6

Public Literature Alignment

Key takeaway: The literature now states the same thing the repository does: AgenticCareerBoost is a traceable system with evidence, not just polished output.

This reconciliation updates public and repository-facing indexes so the formal report set includes this document alongside the guide, refactor retrospective, and earlier sprint reports.

The aligned story is:

- the refactor simplified active structure;
- the review found small live drift and one intentionally discarded draft class;
- the reconciliation fixed the live drift;
- the project preserved evidence while preventing stale drafts from steering future copy;
- tests and validation now guard the corrected shape.

That is the project lore in engineering form: an agentic run is not complete when it produces an artifact. It is complete when the artifact, the trace, the rules, the public surface, and the validation evidence all describe the same thing.

Appendix A

Files Touched by the Reconciliation

- `agents/rules/core/ci-rules.md`
- `site/content/projects.json`
- `agents/reports/tex/Makefile`
- `agents/tests/test_agentic_contracts.py`
- `agents/reports/tex/sprints/agentic-system-evidence-reconciliation.tex`
- `site/files/reports/agentic-system-evidence-reconciliation.pdf`
- `index.html`
- `site/assets/js/os.js`
- `site/assets/js/router.js`
- `README.md`
- `agents/reports/tex/README.md`
- `site/files/reports/README.md`
- `agents/state/logs/agentic-system-evidence-reconciliation-run.md`
- `agents/state/current.md`

Appendix B

Non-Goals

This run does not reopen S-005, restore discarded draft bodies, create new architecture folders, or change branch protection. It made one runtime fix only because browser validation found a route-loading defect in scope for the requested public sanity check. The run remains a reconciliation pass: fix live drift, document evidence, validate, and leave the project easier for the next agent to read.
